A New Synthesis of Difluorodiazirine and the Absolute Reactivity of Difluorocarbene

Robert A. Moss,* Lei Wang, and Karsten Krogh-Jespersen

Department of Chemistry and Chemical Biology, Rutgers, The State University of New Jersey, New Brunswick, New Jersey 08903

Received December 1, 2008; E-mail: moss@rutchem.rutgers.edu

Difluorocarbene (CF₂) is the most stabilized of the dihalocarbenes. Relative to methylene (CH₂), its computed stabilization energy is 62.8 kcal/mol, significantly greater than the stabilization energies of chlorofluorocarbene (CCIF, 42.8 kcal/mol) or dichlorocarbene (CCl₂, 26.5 kcal/mol).¹ Among halo substituents, the fluorines of (singlet) CF₂ provide the strongest electron donation via resonance to the vacant carbenic p orbital and the strongest inductive stabilization of the carbene's σ electrons,² rendering CF₂ the most selective dihalocarbene in additions to alkenes.³ Accordingly, the absolute rate constants and activation parameters for CF₂ additions to alkenes are essential to any comprehensive discussion of carbene/alkene cycloaddition reactions. However, for want of an appropriate, readily accessible, and spectroscopy-friendly precursor, these data have been unavailable.

We require a CF₂ precursor that is compatible with laser flash photolytic (LFP) generation of the carbene. Unfortunately, attempted preparations of the CF₂-phenanthrene adduct, a potential CF2-photoextrusion reagent, have thus far been unsuccessful,⁴ while 10,10-difluorobicyclo[4.3.1]deca-1,3,5-triene, a useful CF₂ photoprecursor for trapping studies, manifests an insufficient quantum yield for LFP experiments.⁵ Difluorodiazirine (1, DFD), on the other hand, is an ideal precursor: it readily generates CF₂ upon photolysis or pyrolysis,⁶ and its innocuous N₂ leaving group is perfect for LFP studies. Unfortunately, classical preparations of DFD via the ferrocene reductive defluorination of bis(difluoroamino)difluoromethane $(2)^7$ or tetrafluoroformamidine $(3)^8$ involve "shatteringly explosive" intermediates.9 DFD is also available by the CsF-mediated rearrangement of difluorocyanamide (F2NCN), but this intermediate too is "highly explosive."10

We are pleased to describe here a new preparation of DFD, the LFP generation of CF_2 , and the first absolute rate constants and activation parameters for condensed phase additions of CF_2 to alkenes. The preparation of DFD is shown in Scheme 1 and is modeled after our recent syntheses of chlorofluorodiazirine¹¹ and dichlorodiazirine.¹² Although all diazirines should be considered dangerous, we have had no explosions with any of the diazirines in Scheme 1. Particularly in solution, these species appear to be quite safe.

The several steps involved in the preparation of 2,4-dinitrophenoxyfluorodiazirine (4) are described in detail in ref 11. The key new reaction in Scheme 1 is the conversion of 4 to DFD (1). An HMPA solution of 4 is slowly added to an excess of Scheme 1. Synthesis of Difluorodiazirine

anhydrous LiF and 15-crown-5 suspended in dry HMPA at 55 °C under a vacuum of 1 Torr. Effervescence signals the generation of DFD, which condenses in pentane in a trap cooled to 77 K.¹³ A UV spectrum of DFD in pentane appears in Figure S-1¹³ and exhibits maxima at 324, 334, 339, 351, and 356 nm, very similar to the UV spectra of chlorofluorodiazirine¹¹ and dichlorodiazirine,¹² and in general agreement with the published gas phase UV spectrum of DFD.^{7b,14} Based on an extinction coefficient of 50 at 356 nm, our approximate isolated yield of DFD is 4%. Despite the low yield, each preparation of DFD from 200 mg of precursor **4** provides enough diazirine for a LFP kinetics experiment.

Scheme 2 offers reasonable mechanisms¹² for the formation of DFD and coproducts **5**–**7**. In Scheme 2a, sequential S_N2' attacks¹⁵ of fluoride ions convert precursor **4** to DFD and 2,4-dinitrophenol (**6**), while (in Scheme 2b) a competitive *ipso* attack of fluoride on **4** leads to the formation of diazirinone (**5**)¹⁶ and 2,4-dinitrofluorobenzene (**7**).

GC analysis of the spent DFD generation residue revealed components **6** and **7** in a 3:1 ratio, suggesting that their "partners," DFD and **5**, were produced in a similar distribution. From the viewpoint of DFD yield optimization, the 3:1 partition between (DFD + **6**) and (**5** + **7**), obtained with LiF/15-crown-5, is the best we encountered. Less favorable partitions were obtained with KF/18-crown-6, NaF/18-crown-6 or 15-crown-5, and LiF/12-crown-4 or 18-crown-6; cf. Table S-1.¹³

We demonstrated the LFP generation of CF₂ from DFD by UV detection of the CF₂ ylides formed with pyridine, isoquinoline, or thioanisole, **8–10**, respectively. Absorptions of **8** and **10** in pentane were observed at 436 and 356 nm, in reasonable agreement with the corresponding calculated absorption maxima at 422 nm (f = 0.33) and 328 m (f = 0.32).¹⁷ A slightly stronger absorption was obtained for isoquinoline ylide **9** at 460 nm (expected at 450 nm, f = 0.48).¹⁸ The LFP-UV spectra of ylides **8–10** appear in Figures S-2–S-4.¹³

CF₂ generated photochemically or thermally from DFD adds to a variety of alkenes.^{6a} Additionally, the *relative* rate constants for additions to tetra-, tri-, di-, and monosubstituted alkenes have been reported.¹⁹ We used the ylide method²⁰ to measure the first *absolute* rate constants for additions of CF₂ to alkenes in solution. The apparent rate of formation of ylide **9** in pentane was accelerated by the addition of an alkene at a constant concentration of isoquinoline. A correlation of the observed rate constant for the formation of **9** vs [alkene] was linear, and its slope gave k_{add} for the addition of CF₂ to the alkene.^{20,21} Rate constants for the additions of CF₂ to tetramethylethylene (TME), trimethylethylene, cyclohexene, and 1-hexene appear in Table 1, where they are compared to analogous data for CClF¹¹ and CCl₂.¹²

CF₂ is clearly electrophilic toward the alkenes of Table 1; k_{add} increases with increasing alkene substitution. However, CF₂ is not much less reactive toward these substrates than CCl₂ or CFCl: $(k_{add})_{CCl_2}$ exceeds $(k_{add})_{CF_2}$ by factors of only 5–19 for the alkenes of Table 1. Even the absolute rate constants for CBr₂ additions to these olefins²² are roughly comparable to those of CCl₂ and <100 times greater than those of CF₂. The significantly greater stability of CF₂ over CFCl or CCl₂ (see above) seems somewhat underexpressed in its absolute reactivity toward alkenes. To obtain a truly substantial rate decrease, we must

Table 1. Absolute Rate Constants for Dihalocarbene Additions ^a								
alkene	$\text{CCl}_2^{b,c}$	CCIF ^c	CF_2^d					
Me ₂ C=CMe ₂	4.7×10^9	1.2×10^9	6.4×10^{8}					
$Me_2C = CHMe$ $c - C_6H_{10}$	2.5×10^{3} 6.4×10^{7}	$3.8 \times 10^{\circ}$ 2.7×10^{7}	1.3×10^{8} 1.4×10^{7}					
$CH_2 = CHC_4H_9$	1.8×10^{7}	1.1×10^{7}	2.4×10^{6}

look to methoxychlorocarbene, where $k_{add} = 4.9 \times 10^3 \text{ M}^{-1} \text{ s}^{-1}$ with TME,²³ representing decelerations of $9.6 \times 10^5 \text{ vs CCl}_2$ and $1.3 \times 10^5 \text{ vs CF}_2$. The reason why the methoxy substituent is more effective than halogens, including fluorine, at moderating carbenic reactivity is complicated and involves considerations of frontier molecular orbital theory and carbene HOMO and LUMO energies.²⁴

The older literature features plentiful predictive discussion about the comparative reactivity of CF₂ and CCl₂.²⁵ The consensus is that alkene additions of CCl₂ should have very low activation energies and be entropy-dominated, whereas additions of CF₂ should be enthalpy-controlled. Our recent studies of CCl₂ and CClF revealed that the additions of both carbenes to TME were entropy-dominated. Additions of CCl₂ to cyclohexene displayed comparable enthalpic and entropic contributions to ΔG^{\ddagger} , while CClF additions were dominated by $\Delta H^{\ddagger.26}$

Here we report initial determinations of the activation parameters for CF₂ additions to TME and cyclohexene; k_{add} was obtained by LFP of DFD in pentane solutions of the alkenes using isoquinoline ylide visualization²⁰ at five temperatures between (ca.) 262 and 305 K. Precise temperatures (±0.1 K) were ascertained at the instant of LFP via a thermocouple immersed in the irradiated solutions. Activation parameters were calculated from ln k_{add} vs 1/*T* correlations using two independent sets of data for each carbene–alkene pair.²¹ The results appear in Table 2, together with analogous findings for CCl₂ and CClF.²⁶ A determination of the activation energy for the addition of CF₂ to TME is shown in Figure 1 as a representative example.²¹

Some anticipated²⁵ trends for these electrophilic dihalocarbenes are well expressed: E_a for either alkene increases in the order of increasing carbene stability, $CCl_2 < CClF < CF_2$, and E_a is greater for additions to cyclohexene than TME. With regard to the $\Delta H^{\dagger}/\Delta S^{\dagger}$ balance for additions to TME, CCl_2 and CClFare entropy-dominated, while enthalpy and entropy are roughly comparable for CF_2 .

The experimental E_a for the addition of CF₂ to ethene has been estimated as ~11-12 kcal/mol^{1,27} and computed at 10.6 kcal/mol,²⁸ consistent with our measured E_a values for the CF₂ additions to TME and cyclohexene. Thus, stripping two alkyl groups from TME (affording a disubstituted alkene like cyclohexene) incurs an increase in E_a from 3 to 7 kcal/mol. A similar E_a increase attending the loss of two alkyl groups from cyclohexene (i.e., to ethene) would bring the E_a to the literature value of ~11 kcal/mol.

An unexpected trend in Table 2 is the apparent increase of ΔS^{\dagger} , parallel to the increases in ΔH^{\dagger} or E_{a} , in the order CCl₂ < CClF < CF₂. The net effect is to decrease the contribution of $T\Delta S^{\dagger}$ to ΔG^{\dagger} as the contribution of ΔH^{\dagger} increases. Thus ΔG^{\dagger} increases (and k_{add} decreases) only in small steps as CCl₂ morphs into CF₂. A priori, one would expect ΔS^{\dagger} to decrease as the carbene's stability increases and its addition reaction transition state becomes later and tighter.²⁵ Hopefully, this situation will be clarified by further research that is now in progress.
